EXPERIMENT NO :- 03

Komal Deolekar	Roll: No :- 14
Shreyash Dhekane	Roll: No :- 16
Tejas Gunjal	Roll: No :- 18

Aim : Topic Finalization

Shortlisted Topics : -
1) Radar using Laser Sensor
2) Distance Measurement using Ultrasonic Sensor
3) Distance Measurement using Laser Sensor

Theory :

1) Radar using Laser Sensor :-
A Radar using a Laser Sensor and Arduino Uno R3 works on the principle of LiDAR (Light Detection and Ranging). It uses a laser sensor to measure the distance and position of objects based on the Time of Flight (ToF) of the laser beam. The Arduino Uno R3 acts as the control unit that processes the signals from the laser sensor and controls the system's operation.

Working :
- A laser sensor generates a narrow beam of light.
- The light reflects off a target and returns to the sensor.
- The Arduino measures the time between the emission and reception of the signal.
- Using the known speed of light (approximately 3×10^8 m/s), the distance is calculated.
- If mounted on a rotating servo, the system can scan a wide area and create a radar-like map.

Component	Description
Arduino Uno R3	Microcontroller board that processes input from the laser sensor and controls the output.
Laser Distance Sensor (e.g., VL53L0X, TF-Luna)	Measures distance using the Time of Flight (ToF) method.
Servo Motor	Rotates the laser sensor to enable 360-degree scanning.
Photodiode/Phototransistor	Detects the reflected laser light and converts it into an electrical signal.
Resistors and Capacitors	Used to stabilize and control the electrical signals.

Power Supply	5V or 9V DC supply for the Arduino and components.
Jumper Wires	For connecting components to the Arduino board.
LCD/LED Display	To display the distance and position of detected objects.
Rotating Platform	Mounts the sensor and allows scanning.
Communication Interface (Optional)	USB or Bluetooth module to transmit data to a computer or mobile device.

2) Distance Measurement using Ultrasonic Sensor :-

Distance measurement using an Ultrasonic Sensor and an Arduino Uno R3 is based on the principle of sound wave reflection and the Time of Flight (ToF) method. Ultrasonic sensors work by emitting high-frequency sound waves (typically around 40 kHz) and measuring the time it takes for the sound waves to reflect back after hitting an object.

Working :

- The ultrasonic sensor consists of two main components:
  - Transmitter – Sends out ultrasonic waves.
  - Receiver – Detects the reflected waves.
- The Arduino measures the time between the transmitted and received signals.
- The distance is calculated using the known speed of sound.

Component	Description
Arduino Uno R3	Microcontroller board to process the sensor data.
Ultrasonic Sensor (e.g., HC-SR04)	Sends and receives ultrasonic waves to measure distance.
Jumper Wires	For connecting the components.
Resistors	Used for signal conditioning and stability.
Power Supply	5V or 9V DC to power the Arduino.
LCD/LED Display (Optional)	To display the measured distance.
Breadboard	For easy circuit prototyping.
Buzzer (Optional)	For alerting when the object is too close.

3) Distance Measurement Using VL53L0X Laser Sensor and Arduino Uno R3

Distance measurement using a VL53L0X Time-of-Flight (ToF) laser sensor and an Arduino Uno R3 works based on the principle of Time of Flight (ToF). The VL53L0X sensor emits an infrared laser pulse toward a target, and the time taken for the pulse to return after reflection is measured. This time delay is used to calculate the distance to the object with high accuracy.

The Arduino Uno processes the signal from the sensor, computes the distance, and displays the result on an output device such as an LCD or a serial monitor. This setup is highly efficient for short-range distance measurement and is widely used in robotics, automation, and obstacle detection.

Working :
- **Laser Emitter:** The VL53L0X emits an infrared laser pulse toward the target.
- **Reflection:** The laser pulse bounces back after hitting the target.
- **Time of Flight (ToF):** The sensor measures the time delay between emission and reception.
- **Distance Calculation:** The Arduino computes the distance using the speed of light and the measured time delay.
- **Output:** The calculated distance is displayed on an LCD or serial monitor.

Components Required:

Component	Description
Arduino Uno R3	Microcontroller board used to process sensor data.
VL53L0X Laser Sensor	ToF sensor that measures distance using infrared.
Jumper Wires	For making electrical connections between components.
Power Supply	5V DC (can be provided by the Arduino).
LCD/LED Display (Optional)	For displaying the measured distance.
Breadboard	For circuit prototyping and testing.
